(Received 10 June 2010; published 29 June 2010)

We investigate the surface Rashba effect for a surface of reduced in-plane symmetry. Formulating a k·p perturbation theory, we show that the Rashba splitting is anisotropic, in agreement with symmetry-based considerations. We show that the anisotropic Rashba splitting is due to the admixture of bulk states of different symmetry to the surface state, and it cannot be explained within the standard theoretical picture supposing just a normal-to-surface variation in the crystal potential. Performing relativistic ab initio calculations we find a remarkably large Rashba anisotropy for an unreconstructed Au(110) surface that is in the experimentally accessible range.

I. INTRODUCTION

Metallic surfaces often exhibit Shockley-type surface states located in a relative band gap of the bulk band structure and forming a two-dimensional electron gas. One of the most intriguing manifestation of spin-orbit coupling (SOC) at surfaces is the splitting of these surface states, known as Rashba splitting.1,2 Such Rashba splitting was observed via photoemission by LaShell et al.3 for the L-gap surface state at Au(111) and explained theoretically in terms of a tight-binding model4 and ab initio electronic structure calculations5,6 but several studies of the Rashba splitting were recently published in on Bi49 and Pb55/H2O849 surfaces, as revealed by recent high-resolution photoelectron spectroscopy experiments.19 In this case, the C2v point-group symmetry of the system not only implies the asymmetry of the effective mass, m∗ ≠ m∗, (for the crystal axes see Fig. 1) but, in leading order in k, representation theory also predicts the following simple form of the effective Hamiltonian:18

The simplest way to understand the origin of the Rashba effect is to take nearly free electrons, confined by a crystal potential, V(r) = V(z), and having a plane-wavelike wave function, \( \psi_{\mathbf{k}}(\mathbf{r}) = e^{i\mathbf{k}\cdot\mathbf{r}} \phi(z) \chi_s \), with \( \chi_s \) some spinor eigenfunctions, and \( \mathbf{k} \) the momentum parallel to the surface. The crystal potential \( V(z) \) obviously produces an electric field, \( \mathbf{E} \), perpendicular to the surface, which, in the presence of spin-orbit interaction leads to the following spin-orbit term in the effective Hamiltonian:

\[
H_R(\mathbf{k}) = \alpha_R (k_y \sigma_x - k_x \sigma_y),
\]

called Rashba-Hamiltonian. In Eq. (1), \( \sigma_i \) denote the Pauli matrices and \( \alpha_R = \frac{\hbar}{2m_e} \left( \frac{\varepsilon}{4\pi\epsilon_0 c} \right)^{1/2} \) is the so-called Rashba parameter. The eigenvalue problem can then easily be solved, resulting in a splitting of the spin degeneracy of the surface states, \( \varepsilon_s(\mathbf{k}) = \frac{\hbar^2}{2m_e} k^2 \pm E_R |\mathbf{k}| \), with \( m^* \) the effective mass of the surface electrons.3,6 Clearly, the above dispersion is isotropic in \( k \) space, hence we term it as isotropic Rashba splitting.

Although real systems cannot be described in terms of free electrons, and for quantitative estimates of \( \alpha_R \) the atomic structure of the potential needs to be taken into account, the form of the Rashba interaction, Eq. (1), is very robust for surfaces of high point-group symmetry such as \( C_{3v} \), or \( C_4v \).

The situation is, however, quite different for surfaces (or points in the surface Brillouin zone) of reduced symmetry. Such Shockley-type surface states emerge, e.g., around the \( \overline{Y} \) point of the surface Brillouin zone of unreconstructed and \((2 \times 1)\) reconstructed Au(110) surfaces, as revealed by recent high-resolution photoelectron spectroscopy experiments.19 In this case, the \( C_{2v} \) point-group symmetry of the system not only implies the asymmetry of the effective mass, \( m^* \neq m^* \), but, in leading order in \( k \), representation theory also predicts the following simple form of the effective Hamiltonian:18

\[
H_R(\mathbf{k}) = \alpha_R (k_y \sigma_x - k_x \sigma_y),
\]

FIG. 1. (Color online) Left: sketch of the fcc(110) surface Brillouin zone. The dark area denotes the projection of the L gap of bulk Au. Right: structure of the surface energy spectrum in the absence of SO interaction, along the line \( \mathbf{k} = (k_x, 0) \). Surface states in the relative gap with \( \mathbf{k} \neq 0 \) can be built up from states indicated by the thick black lines and the black circle at \( \mathbf{k} = 0 \). Note that \( \mathbf{k} = 0 \) corresponds to the \( \overline{Y} \) point of the Brillouin zone, see Eq. (3).
\[ H(\mathbf{k}) = \varepsilon_0 + \frac{\hbar^2 k_x^2}{2m_x^2} + \frac{\hbar^2 k_y^2}{2m_y^2} + \alpha_{R,x} k_x \sigma_y - \alpha_{R,y} k_y \sigma_x. \] (2)

The above expression can easily be justified by simple symmetry analysis, just by noticing that \( \sigma_x \) and \(-\sigma_x \) transform as \( p_x \) and \( p_y \) under the operations of the double groups of \( C_{2v} \) and \( C_{4v} \). From this observation it also follows that in case of \( C_{4v} \) point-group symmetry \( \alpha_{R,x} = \alpha_{R,y} \) must be satisfied, and Hamiltonian (1) is recovered.20

Although the above form of the Rashba interaction has been predicted in Ref. 18, no microscopic theory has been constructed so far to support it. While previous \textit{ab initio} calculations19,21 did find a Rashba splitting of the Au(110) surface state, they focused only on the dispersion along the \( \bar{\Gamma}\bar{Y} \) direction, and therefore the anisotropy of the Rashba term remained unnoticed. In the present paper, we provide such a microscopic analysis for an Au(110) surface with \( C_{2v} \) point-group symmetry. First, constructing a \( k \cdot p \) perturbation theory for the surface states we show that the above anisotropic Rashba structure appears naturally and is due to the finite momentum mixing of the bulk \( p \) states to the surface state. We also perform \textit{ab initio} calculations of the Rashba-split surface state of an unreconstructed Au(110) surface and confirm with a high numerical accuracy that there is a large anisotropy in \( k \) space, \( \alpha_{R,x} \sim 5 \alpha_{R,y} \), in agreement with Eq. (2). The predicted anisotropic Rashba splittings turn out to be within the range of experimental accuracy.

II. \( k \cdot p \) PERTURBATION THEORY OF THE RASHBA SPLITTING

Bloch states of Au(110) can be characterized by a surface momentum and can thus be written as

\[ \psi_{Q,k}(\mathbf{r}) = e^{iQ \cdot \mathbf{r}} \phi_{Q,k}(\mathbf{r}) \] (3)

with the momentum \( Q \) measured with respect to the momentum \( \mathbf{Q} \) associated with the \( \bar{\Gamma} \) point of the surface Brillouin zone. Here the functions \( \phi_{Q,k}(\mathbf{r}) \) are lattice antiperiodic in the \( x \) direction while they are lattice periodic in the \( y \) direction of the \((110)\) plane, see Fig. 1. For any given momentum, \( \mathbf{k} \), there exist an infinite number (continuum) of eigenstates, the energy of which \( \varepsilon_k \) is determined by the condition that the states \( \psi_{Q,k} \) be eigenstates of the Hamiltonian, \( H = \frac{p^2}{2m} + V(\mathbf{r}) + H_{SO} \), with \( H_{SO} \) denoting the spin-orbit coupling.

\[ H_{SO}(\mathbf{r}) = \frac{\hbar v_{\text{so}}}{4m^2 c^2} [\nabla V(\mathbf{r}) \times \mathbf{p}] \sigma. \] (4)

As a consequence, the functions \( \phi_{Q,k} \) must satisfy the equation,

\[ \left[ \frac{\mathbf{p}^2}{2m} + V(\mathbf{r}) + \frac{\hbar^2 k_x^2}{2m_x^2} + \frac{\hbar k \cdot \mathbf{p}}{m} + \tilde{H}_{SO}(\mathbf{k}, \mathbf{r}) \right] \phi_{Q,k}(\mathbf{r}) = \varepsilon_k \phi_{Q,k}(\mathbf{r}) \] (5)

with \( \tilde{H}_{SO}(\mathbf{k}, \mathbf{r}) \) being the effective SO coupling.

\[ \tilde{H}_{SO}(\mathbf{k}, \mathbf{r}) = H_{SO}(\mathbf{r}) + \frac{\hbar v_{\text{so}}}{4m^2 c^2} [\nabla V(\mathbf{r}) \times \mathbf{p}] \sigma. \] (6)

Similar to Bloch wave functions, for any fixed momentum, \( \mathbf{k} \), (and for any value of \( \tilde{H}_{SO} \)) the functions \( \phi_{Q,k} \) form a complete set for functions having the previously mentioned periodicity property. In the spirit of \( k \cdot p \) perturbation theory, we can thus take the complete set of \( \mathbf{k} = 0 \) and \( \tilde{H}_{SO} = 0 \) solutions, satisfying

\[ \left[ \frac{\mathbf{p}^2}{2m} + V(\mathbf{r}) \right] \phi_{0,i}(\mathbf{r}) = \varepsilon_{0,i} \phi_{0,i}(\mathbf{r}) \] (7)

and expand \( \phi_{Q,k} \) in terms of these. Here we classified the solutions according to the four one-dimensional irreducible representations of the \( C_{2v} \) symmetry associated with the point \( \bar{Y} \), \( i \in \{1, x, y, xy\} \), and labeled solutions of a given symmetry by \( n_i \). As shown in Fig. 1, the spectrum contains a discrete surface state of \( s \) symmetry and the projected bulk continuum forming the gap. Let us denote the \( \mathbf{k} = 0 \) surface state by \( \phi_0 \) and its eigenenergy by \( \varepsilon_0 \). Then states with \( \mathbf{k} \neq 0 \) but with \( \tilde{H}_{SO} = 0 \) can be expressed in terms of the states \( \phi_{0,i} \) by performing second-order perturbation theory in \( \mathbf{k} \), which amounts in a surface state

\[ \phi_i^{(0)} = \phi_0 + \frac{\hbar v_{\text{so}}}{4m^2 c^2} \sum_{n_i} \frac{|\phi_{0,i}(\mathbf{r})|^2}{\varepsilon_{0,i}} \phi_{i,n} \] (8)

with approximate dispersion

\[ \varepsilon_{0,i} = \varepsilon_0 + \frac{\hbar^2 k_x^2}{2m_x^2} + \frac{\hbar^2 k_y^2}{2m_y^2}. \] (9)

\[ \frac{1}{m_x^2} = \frac{1}{m} + 2 \sum_{n_i} \frac{|\phi_{0,i}(\mathbf{r})|^2}{\varepsilon_0 - \varepsilon_{0,i}}. \] (10)

The index 0 in \( \varepsilon_{0,i} \) and \( |\phi_{0,i}^{(0)}| \) is meant to remind us to the absence of SO interaction.

To obtain the surface states, \( |\phi_0(\mathbf{r})| \), we then carry out first-order perturbation theory with the SOC operator, \( \tilde{H}_{SO} \), using the states \( |\phi_{0,i}^{(0)}| \) as a starting point. Keeping just contributions linear in \( \mathbf{k} \) we get two terms to the effective Rashba Hamiltonian. The second term in Eq. (6) gives rise to the usual isotropic Rashba model,

\[ H_{R}^{\text{iso}}(\mathbf{k}) = \alpha_{R} (\mathbf{e}_z \times \mathbf{k}) \cdot \mathbf{\sigma} \] (11)

with \( \alpha_{R} = \frac{\hbar^2}{4m^2 c^2} \langle \phi_0 | \hat{\alpha}_z \hat{V}/\hat{\alpha}_z | \phi_0 \rangle \). The term \( H_{SO} \) in Eq. (6), however, gives also a finite contribution due to the admixture of \( p_{x,y} \) states from the continuum and, in fact, this is precisely the term that leads to an anisotropic Rashba coupling,

\[ H_{R}^{\text{aniso}}(\mathbf{k}) = \frac{\hbar}{4m^2 c^2} \sum_{i=x,y} \sum_{n_i} \frac{\langle \phi_{i,n} | p_i | \phi_0 \rangle (\langle \phi_0 | \mathbf{a} | \phi_{i,n} \rangle \mathbf{\alpha} + \text{H.c.})}{\varepsilon_0 - \varepsilon_{0,i}} \] (12)

where we defined the (axial) vector operator related to SOC, \( \mathbf{a} = \frac{\hbar v_{\text{so}}}{4m^2 c^2} [\nabla V(\mathbf{r}) \times \mathbf{p}] \). Using the symmetry of the unperturbed wave functions, a particularly simple form of the above anisotropic Rashba coupling may be obtained.

235438-2
isotropic Rashba Hamiltonian can be obtained,
\[ H^\text{Rashba}\,(\mathbf{k}) = \lambda_\perp \hat{y} \sigma_x + \lambda_\parallel \hat{y} \sigma_x \]  
with the coefficient \( \lambda_\perp \) expressed as
\[ \lambda_\perp = \frac{2\hbar^2}{\bar{m}_x} \sum_{m} A_{m} \text{Re}(\langle \phi_{\alpha,m} | \rho_{\alpha} | \phi_{\alpha,m} \rangle) / (\varepsilon_0 - \varepsilon_{\alpha,m}) \]  
and \( \lambda_\parallel \) given by a similar expression. The structure of the combined terms, Eqs. (11) and (13), is identical to the one obtained by symmetry analysis, Eq. (2), with \( \alpha_{R,x} = \alpha_{R} + \lambda_\perp \) and \( \alpha_{R,y} = \alpha_{R} - \lambda_\perp \). It should be noted that Eq. (13) can be transformed into the familiar Rashba-Dresselhaus Hamiltonian used in the context of semiconductor quantum wells in the absence of bulk or interface inversion symmetry. 14,22,23

This formal similarity is due to the point-group symmetry imposing \( \lambda_\perp = -\lambda_\parallel \), the Dresselhaus coupling vanishes, whereas the term, Eq. (13), arising from the mixing of the surface state with bulk states, continues to contribute to the isotropic Rashba splitting.

III. AB INITIO CALCULATIONS FOR Au(110)

To obtain a quantitative estimate of the parameters \( \alpha_{R,x,y} \) and the induced Rashba splittings, we performed calculations of the surface states of unreconstructed Au(110) surface near the \( \bar{Y} \) point of the surface Brillouin zone, using the relativistic screened Korringa-Kohn-Rostoker method. 24 Noticeably, in this method no slab or supercell approach is used as the substrate is modeled by a perfect semi-infinite bulk system. The local spin-density approximation as parametrized by Vosko et al. 25 was applied, the effective potentials and fields were treated within the atomic sphere approximation (ASA) with an angular momentum cutoff of \( \ell_{\text{max}} = 2 \). The energy integrations were performed by sampling 16 points on a semicircular path in the upper complex semiplane and for the necessary \( k \) integrations we selected 64 \( k \) points in the irreducible segment of the surface Brillouin zone.

The computed dispersion relations along the \( \bar{Y}\bar{Y} \) (\( x \)) and the \( \bar{Y}\bar{S} \) (\( y \)) directions are plotted in Fig. 2. The maximum binding energy, \( \varepsilon_{\text{B}} \approx 370 \text{ meV} \), is by about 200 meV less than the measured value 19 and other theoretical values. 19,21 This deviation is mostly caused by the ASA and the angular momentum cutoff, \( \ell_{\text{max}} = 2 \), which resulted in some error for the determination of the Fermi level and the vacuum potential.

The nearly free-electronlike, parabolic shape of the dispersion as well as the Rashba splitting being remarkably different along the two directions is obvious from Fig. 2, and a detailed analysis confirms this impression: the numerical results are very well fitted by the dispersions \( \varepsilon_{\perp}(\mathbf{k}) = \varepsilon_0 + \frac{k_y^2}{2m_\perp} + \sqrt{\alpha_{R,x}^2 k_x^2 + \alpha_{R,y}^2 k_y^2} \), obtained by diagonalizing the approximate Hamiltonian, Eq. (2), with the fitting parameters, \( m_\perp = 0.11 m, \quad m_\parallel = 0.32 m, \quad \alpha_{R,x} = 0.8 \text{ eV Å}, \quad \alpha_{R,y} = 0.17 \text{ eV Å} \). The obtained effective mass along the \( \bar{Y}\bar{S} \) direction is in satisfactory agreement with the measured value, \( m_\parallel = 0.25 m \). 19 The effective mass along \( \bar{Y}\bar{Y} \), \( m_\perp \), is only about one third of \( m_\parallel \), which is the consequence that the states at the lower bulk band edge are mainly of \( p_x \) and \( p_y \) characters [see Eq. (9)]. Note that the energy separation of the surface state at the \( \bar{Y} \) point is 0.8 eV and 3.4 eV with respect to the lower and upper bulk band edges, respectively, implying a strong admixture of “electron” states from the continuum below the surface state.

One of the most astonishing results of these numerical calculations is the remarkably large anisotropy of the Rashba parameters, \( \alpha_{R,x} \approx 5 \alpha_{R,y} \). In view of Eq. (14), this observation can also be explained with the absence of \( p_x \) states at the lower bulk band edge. This result also correlates with the results of the effective mass: the smaller value of \( m_\perp \) indicates a stronger admixture of \( p_x \) states, also responsible for the stronger renormalization of \( \alpha_{R,x} \).

In order to attest the above effect, it is worth to compare the Rashba splitting of the surface states for Au(110) with those of the well-established Au(111) case. From our corresponding calculations we conclude that \( \alpha_{R,x} \) for Au(110) is even larger than \( \alpha_{R} \) for the L-gap state of Au(111), 0.57 eV Å. This latter value is though considerably larger than the experimental one, 0.4 eV Å, 26 which correlates with the theoretically computed effective mass, \( m^* \sim 0.19 m \), being too small as compared to the experimentally observed value, \( m^* \sim 0.25 m \). The computed Fermi wave numbers, \( k_F = 0.160 \) and 0.189 Å\(^{-1}\), on the other hand, are almost in perfect agreement with the measured values. 26 Nevertheless, based on the discrepancy regarding the value of the effective masses, we expect that our theoretical calculations for Au(110) somewhat overestimate the Rashba parameters, \( \alpha_{R,x,y} \).

The anisotropic Rashba coupling together with the anisotropic effective mass gives rise to a Rashba-split Fermi surface for the surface states, as shown in Fig. 3. The Rashba splitting along \( \bar{Y}\bar{S} \), \( \Delta k_y = 0.017 \text{ Å}^{-1} \), is in the order of the
The Rashba interaction gets an anisotropic part in first order and the Rashba splitting should be experimentally observable along the $\bar{\Gamma}Y$ direction.

In summary, we constructed a $k\cdot p$ perturbation theory for surface states in the presence of SO coupling and derived a generalized Rashba Hamiltonian for (nearly free) electrons on metal surfaces. We found that in case of $\mathcal{C}_{2h}$ symmetry, the Rashba interaction gets an anisotropic part in first order of $\mathbf{k}$, which for Au(110) is found to dominate over the additional, well-known symmetric term. The anisotropic Rashba splitting should pertain to the surface states of a missing-row reconstructed Au(110) surface, it could be more difficult to detect experimentally because these surface states lie above the Fermi level.
