Linear regression

$$\begin{aligned}y &= \alpha + \beta x \\ \hat{\beta} &= \frac{\sum(x_i - \bar{x})(y_i - \bar{y})}{\sum(x_i - \bar{x})^2} = \frac{\overline{xy} - \bar{x}\bar{y}}{\overline{x^2} - \bar{x}^2} \\ \hat{\alpha} &= \bar{y} - \hat{\beta}\bar{x} \\ \rho &= \frac{\overline{xy}}{\sqrt{\overline{x^2}\overline{y^2}}}\end{aligned}\tag{1}$$

Fitting

Hubble original fit:

Fitting

Hubble change in time:

Fitting

Hubble change in time:

Copyright J. Huchra 2008

Finite size scaling

- ▶ Correlation length

$$\xi \propto |T - T_c|^{-\nu}$$

- ▶ If L is finite ξ cannot be larger than L

$$L \propto |T(L) - T_c|^{-\nu}$$

- ▶ The position and the width of the transition

$$|T(L) - T_c| \propto L^{-1/\nu}$$

$$\sigma(L) \propto L^{-1/\nu}$$

Ising model susceptibility

Three parameter fit: Ising model

- ▶ Theory: $\nu = 1$, $T_c \simeq 2.27$

Finite size scaling: Ising model

► Theory: $\nu = 1$, $T_c \simeq 2.27$

Metropolis algorithm

(Metropoli-Rosenbluth-Rosenbluth-Teller-Teller=MR²T² algorithm)

- ▶ Sequence of configurations using a Markov chain
- ▶ Configuration is generated from the previous one
- ▶ Transition probability: equilibrium probability
- ▶ Detailed balance:

$$P(x)P(x \rightarrow x') = P(x')P(x' \rightarrow x)$$

- ▶ Rewritten:

$$\frac{P(x \rightarrow x')}{P(x' \rightarrow x)} = \frac{P(x')}{P(x)} = e^{-\beta\Delta E}$$

- ▶ Only the ration of transition probabilities are fixed

Metropolis algorithm

(Metropoli-Rosenbluth-Rosenbluth-Teller-Teller=MR²T² algorithm)

$$\frac{P(x \rightarrow x')}{P(x' \rightarrow x)} = \frac{P(x')}{P(x)} = e^{-\beta\Delta E}$$

► Metropolis:

$$P(x \rightarrow x') = \begin{cases} e^{-\beta\Delta E} & \text{if } \Delta E > 0 \\ 1 & \text{otherwise} \end{cases}$$

► Symmetric:

$$P(x \rightarrow x') = \frac{e^{-\beta\Delta E}}{1 + e^{-\beta\Delta E}}$$

Metropolis algorithm

Recipes:

- ▶ Choose an elementary step $x \rightarrow x'$
- ▶ Calculate ΔE
- ▶ Calculate $P(x \rightarrow x')$
- ▶ Generate random number $r \in [0, 1]$
- ▶ If $r < P(x \rightarrow x')$ then new state is x' ; otherwise it remains x
- ▶ Increase time
- ▶ Measure what you want
- ▶ Restart

Metropolis algorithm, proposal probability

Transition probability:

$$P(x \rightarrow x') = g(x \rightarrow x')A(x \rightarrow x')$$

- ▶ $g(x \rightarrow x')$: proposal probability
 - ▶ Generally uniform
 - ▶ If different interactions are present then it must be incorporated
- ▶ $A(x \rightarrow x')$: acceptance probability
 - ▶ Metropolis
 - ▶ Symmetric

Metropolis, *proof*

State flow

Let $E > E'$:

- ▶ $x \rightarrow x'$

$$P(x)g(x \rightarrow x')A(x \rightarrow x') = P(x)$$

- ▶ $x' \rightarrow x$

$$P(x')g(x' \rightarrow x)A(x' \rightarrow x) = P(x')e^{-\beta\Delta E}$$

- ▶ In equilibrium they are equal:

$$\frac{P(x)}{P(x')} = e^{\beta\Delta E}$$

- ▶ What we wanted.

Do we need optimization?

- ▶ Correlation length ξ
- ▶ Characteristic time τ_{char}
- ▶ Dynamical exponent z

$$\tau_{\text{char}} \propto \xi^z$$

- ▶ For 2d Ising model $z \simeq 2.17$
- ▶ Simulation time:

$$t_{\text{CPU}} \sim L^{d+z}$$

We need more effective algorithms!

Multri-spin algorithm for 2d Ising model

History...

- ▶ Operations:
 - ▶ Check if neighbor is parallel: XOR
 - ▶ sum of antiparallel spins: sum of previous XOR
- ▶ Result: discrete energy difference can be 0, 1, 2, 3, 4

Metropolis	0	1	2	3	4
$\Delta E/J$	8	4	0	4	8
$P(x \rightarrow x')$	$\exp(-8\beta)$	$\exp(-4\beta)$	0	0	0

- ▶ (of course $P(x \rightarrow x')$ in array)
- ▶ 4 bit is enough to store result
- ▶ Use every fourth bit to store a spin.

Multri-spin algorithm for 2d Ising model

- ▶ Historical solution
 - ▶ Every fourth bit in the integer is a spin
 - ▶ To get neighbors bit shift operation must be made
 - ▶ We get `sizeof(int)/4` bits at once
 - ▶ Go through the sample in a typewriter style
 - ▶ Nowadays may even be slower as array operations are fast
- ▶ Use it for ensemble average
 - ▶ One member of the array contains the spin of one position
 - ▶ Multiple simulation instances
 - ▶ With Metropolis algorithm few random numbers are needed (at high T)
- ▶ Does not really matter only factors can be won, $t_{\text{CPU}} \sim L^{d+z}$ still holds

Cluster algorithm

- ▶ Flip more spins together. How?
- ▶ The solution – based on an old relationship between the percolation and the Potts model – is that we consider the spin configuration as a correlated site percolation problem
- ▶ Ising cluster: a percolating cluster of parallel spins
- ▶ Ising droplets: a percolating subset of an Ising cluster
 $p_B = 1 - \exp(-2\beta J)$

Ising cluster

Ising configuration

Ising „droplets”

Swendsen-Wang algorithm

- ▶ Take an Ising configuration
- ▶ With probability $p_B = 1 - \exp(-2\beta J)$ make connection between *parallel* spins
- ▶ Identify the droplets by Hoshen-Kopelman algorithm
- ▶ Flip each droplet with probability: $1/2$ ($h = 0$)
- ▶ Repeat it over

Wolff algorithm

1. Add a random spin to a list of active spins
2. Take a spin from the active list
3. Add each parallel neighboring (not yet visited) spin with probability $p_B = 1 - \exp(-2\beta J)$ to the list of active spins
4. If list of active spins is not empty go to 2.
5. Flip all active spins

A Wolff droplet (gray)
before flipping

a

The new configuration
The droplet contour is
still shown, though the
bonds are eliminated
after flipping

Wolff code

```
bool **cluster;           // cluster[i][j] = true if i,j belongs
double addProbability;    // 1 - e(-2J/kT)

void initializeClusterVariables() {

    // allocate 2-D array for spin cluster labels
    cluster = new bool* [Lx];
    for (int i = 0; i < Lx; i++)
        cluster[i] = new bool [Ly];

    // compute the probability to add a like spin to the cluster
    addProbability = 1 - exp(-2*J/T);
}
```

Wolff code

```
// declare functions to implement Wolff algorithm
void growCluster(int i, int j, int clusterSpin);
void tryAdd(int i, int j, int clusterSpin);

void oneMonteCarloStep() {

    // no cluster defined so clear the cluster array
    for (int i = 0; i < Lx; i++)
    for (int j = 0; j < Ly; j++)
        cluster[i][j] = false;

    // choose a random spin and grow a cluster
    int i = int(qadran() * Lx);
    int j = int(qadran() * Ly);
    growCluster(i, j, s[i][j]);

    ++steps;
}
```

Wolff code

```
void growCluster(int i, int j, int clusterSpin) {  
  
    // mark the spin as belonging to the cluster and flip it  
    cluster[i][j] = true;  
    s[i][j] = -s[i][j];  
  
    // find the indices of the 4 neighbors  
    // assuming periodic boundary conditions  
    int iPrev = i == 0 ? Lx-1 : i-1;  
    int iNext = i == Lx-1 ? 0 : i+1;  
    int jPrev = j == 0 ? Ly-1 : j-1;  
    int jNext = j == Ly-1 ? 0 : j+1;  
  
    // if the neighbor spin does not belong to the  
    // cluster, then try to add it to the cluster  
    if (!cluster[iPrev][j])  
        tryAdd(iPrev, j, clusterSpin);  
    if (!cluster[iNext][j])  
        tryAdd(iNext, j, clusterSpin);  
    if (!cluster[i][jPrev])  
        tryAdd(i, jPrev, clusterSpin);  
  
    if (!cluster[i][jNext])  
        tryAdd(i, jNext, clusterSpin);  
}
```

Wolff code

```
void growCluster(int i, int j, int clusterSpin) {

    // mark the spin as belonging to the cluster and flip it
    cluster[i][j] = true;
    s[i][j] = -s[i][j];

    // find the indices of the 4 neighbors
    // assuming periodic boundary conditions
    int iPrev = i == 0 ? Lx-1 : i-1;
    int iNext = i == Lx-1 ? 0 : i+1;
    int jPrev = j == 0 ? Ly-1 : j-1;
    int jNext = j == Ly-1 ? 0 : j+1;

    // if the neighbor spin does not belong to the
    // cluster, then try to add it to the cluster
    if (!cluster[iPrev][j])
        tryAdd(iPrev, j, clusterSpin);
    if (!cluster[iNext][j])
        tryAdd(iNext, j, clusterSpin);
    if (!cluster[i][jPrev])
        tryAdd(i, jPrev, clusterSpin);

    if (!cluster[i][jNext])
        tryAdd(i, jNext, clusterSpin);
}

void tryAdd(int i, int j, int clusterSpin) {
    if (s[i][j] == clusterSpin)
        if (qdran() < addProbability)
            growCluster(i, j, clusterSpin);
}
```

Comparison magnetization

Comparison magnetization

Comparison magnetization

Comparison magnetization

Comparison magnetization

Wolff algorithm *proof*

- ▶ Energy:
 - ▶ Exterior
 - ▶ Interior
 - ▶ Boundary
- ▶ We modify $g(x \rightarrow x')$ to be exactly $\exp(-\Delta E\beta)$ thus $P(x \rightarrow x') = 1$
- ▶ Good for parallelization!

Other ensembles

Microcanonical ensemble

- ▶ Daemon with bag with tolerance (both directions)
 - ▶ Pick a move, and calculate energy change
 - ▶ If energy change does not fit into bag reject it
 - ▶ Otherwise add energy change to bag
- ▶ In case of conservation the dynamic exponent z is larger!

Conserved order parameter: Kawasaki dynamics

- ▶ Elementary step:
 - ▶ Exchange up-down spin pairs (can be anywhere) simultaneously
 - ▶ Apply Metropolis to net energy change!
 - ▶ Diffusive dynamics is more physical: pick neighboring spins
- ▶ In case of conservation the dynamic exponent z is larger!
