

# Simulations in Statistical Physics

## Course for MSc physics students

Janos Török

Department of Theoretical Physics

October 28, 2014

# Metropolis algorithm

(Metropoli-Rosenbluth-Rosenbluth-Teller-Teller=MR<sup>2</sup>T<sup>2</sup> algorithm)

- ▶ Sequence of configurations using a Markov chain
- ▶ Configuration is generated from the previous one
- ▶ Transition probability: equilibrium probability
- ▶ Detailed balance:

$$P(x)W(x \rightarrow x') = P(x')W(x' \rightarrow x)$$

- ▶ Rewritten:

$$\frac{W(x \rightarrow x')}{W(x' \rightarrow x)} = \frac{P(x')}{P(x)} = e^{-\beta\Delta E}$$

- ▶ Only the ration of transition probabilities are fixed

# Metropolis algorithm

(Metropoli-Rosenbluth-Rosenbluth-Teller-Teller=MR<sup>2</sup>T<sup>2</sup> algorithm)

$$\frac{W(x \rightarrow x')}{W(x' \rightarrow x)} = \frac{P(x')}{P(x)} = e^{-\beta\Delta E}$$

- ▶ Metropolis:

$$W(x \rightarrow x') = \begin{cases} e^{-\beta\Delta E} & \text{if } \Delta E > 0 \\ 1 & \text{otherwise} \end{cases}$$

- ▶ Symmetric:

$$W(x \rightarrow x') = \frac{e^{-\beta\Delta E}}{1 + e^{-\beta\Delta E}}$$

# Metropolis algorithm

Recipes:

- ▶ Choose an elementary step  $x \rightarrow x'$
- ▶ Calculate  $\Delta E$
- ▶ Calculate  $W(x \rightarrow x')$
- ▶ Generate random number  $r \in [0, 1]$
- ▶ If  $r < W(x \rightarrow x')$  then new state is  $x'$ ; otherwise it remains  $x$
- ▶ Increase time
- ▶ Measure what you want
- ▶ Restart

# Metropolis algorithm, proposal probability

Transition probability:

$$W(x \rightarrow x') = g(x \rightarrow x')A(x \rightarrow x')$$

- ▶  $g(x \rightarrow x')$ : proposal probability
  - ▶ Generally uniform
  - ▶ If different interactions are present then it must be incorporated
- ▶  $A(x \rightarrow x')$ : acceptance probability
  - ▶ Metropolis
  - ▶ Symmetric

## Metropolis, *proof*

State flow

Let  $E > E'$ :

- ▶  $x \rightarrow x'$

$$P(x)g(x \rightarrow x')A(x \rightarrow x') = P(x)$$

- ▶  $x' \rightarrow x$

$$P(x')g(x' \rightarrow x)A(x' \rightarrow x) = P(x')e^{-\beta\Delta E}$$

- ▶ In equilibrium they are equal:

$$\frac{P(x)}{P(x')} = e^{\beta\Delta E}$$

- ▶ What we wanted.

# Do we need optimization?

- ▶ Correlation length  $\xi$
- ▶ Characteristic time  $\tau_{\text{char}}$
- ▶ Dynamical exponent  $z$

$$\tau_{\text{char}} \propto \xi^z$$

- ▶ For 2d Ising model  $z \simeq 2.17$
- ▶ Simulation time:

$$t_{\text{CPU}} \sim L^{d+z}$$

We need more effective algorithms!

# Multri-spin algorithm for 2d Ising model

## History...

- ▶ Operations:
  - ▶ Check if neighbor is parallel: XOR
  - ▶ sum of antiparallel spins: sum of previous XOR
- ▶ Result: discrete energy difference can be 0, 1, 2, 3, 4

Metropolis	0	1	2	3	4
$\Delta E/J$	8	4	0	4	8
$W(x \rightarrow x')$	$\exp(-8\beta)$	$\exp(-4\beta)$	1	1	1

- ▶ (of course  $W(x \rightarrow x')$  in array)
- ▶ 3 bit is enough to store result in 2d and 3d
- ▶ Use every fourth bit to store a spin.

# Multri-spin algorithm for 2d Ising model

- ▶ Historical solution
  - ▶ Every fourth bit in the integer is a spin
  - ▶ We get `sizeof(int)/4` bits at once
  - ▶ Special bit order

NxN		8 bit integer		L=N/2	
1	L+1	2	L+2	3	L+3
N+1	N+L+1	N+2	N+L+2	N+3	N+L+3
2N+1	2N+L+1	2N+2	2N+L+2	2N+3	N+L+3

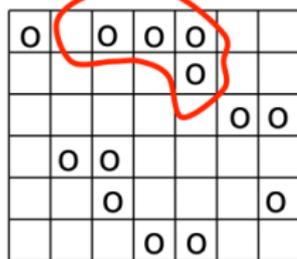

# Multri-spin algorithm for 2d Ising model

- ▶ Historical solution
  - ▶ Every fourth bit in the integer is a spin
  - ▶ We get `sizeof(int)/4` bits at once
  - ▶ Special bit order
  - ▶ Nowadays may even be slower as array operations are fast
- ▶ Use it for ensemble average
  - ▶ One member of the array contains the spin of one position
  - ▶ Multiple simulation instances
  - ▶ With Metropolis algorithm few random numbers are needed (at high  $T$ )
- ▶ Does not really matter only factors can be won,  $t_{\text{CPU}} \sim L^{d+z}$  still holds

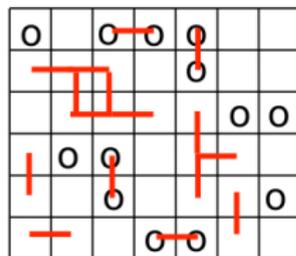

## Cluster algorithm

- ▶ Flip more spins together. How?
- ▶ The solution – based on an old relationship between the percolation and the Potts model – is that we consider the spin configuration as a correlated site percolation problem
- ▶ Ising cluster: a percolating cluster of parallel spins
- ▶ Ising droplets: a percolating subset of an Ising cluster  
 $p_B = 1 - \exp(-2\beta J)$

### Ising cluster

Ising configuration

Ising „droplets”

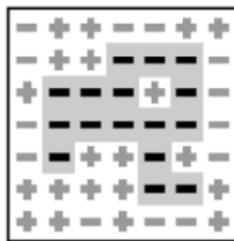

## Swendsen-Wang algorithm

- ▶ Take an Ising configuration
- ▶ With probability  $p_B = 1 - \exp(-2\beta J)$  make connection between *parallel* spins
- ▶ Identify the droplets by Hoshen-Kopelman algorithm
- ▶ Flip each droplet with probability:  $1/2$  ( $h = 0$ )
- ▶ Repeat it over

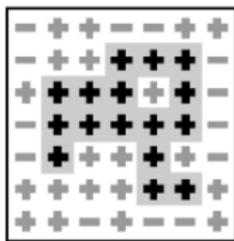

# Wolff algorithm

1. Add a random spin to a list of active spins
2. Take a spin from the active list
3. Add each parallel neighboring (not yet visited) spin with probability  $p_B = 1 - \exp(-2\beta J)$  to the list of active spins
4. If list of active spins is not empty go to 2.
5. Flip all active spins

A Wolff droplet (gray)  
before flipping

a

b

The new configuration  
The droplet contour is  
still shown, though the  
bonds are eliminated  
after flipping

## Wolff algorithm *proof*

- ▶ Detailed balance:

$$P^{eq}(x)W(x \rightarrow x') = P^{eq}(x')W(x' \rightarrow x)$$

- ▶ Metropolis:

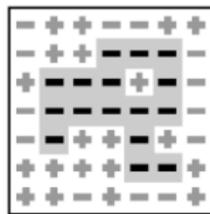

$$W(x \rightarrow x') = \min \left\{ 1, \frac{P^{eq}(x)}{P^{eq}(x')} \right\}$$

- ▶ Split  $W$  into acceptance  $A$  and proposal  $g$  probability

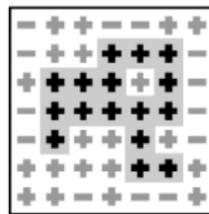

$$A(x \rightarrow x') = \min \left\{ 1, \frac{P^{eq}(x)g(x' \rightarrow x)}{P^{eq}(x')g(x \rightarrow x')} \right\}$$

# Wolff algorithm *proof*

A Wolff droplet (gray)  
before flipping

a

b

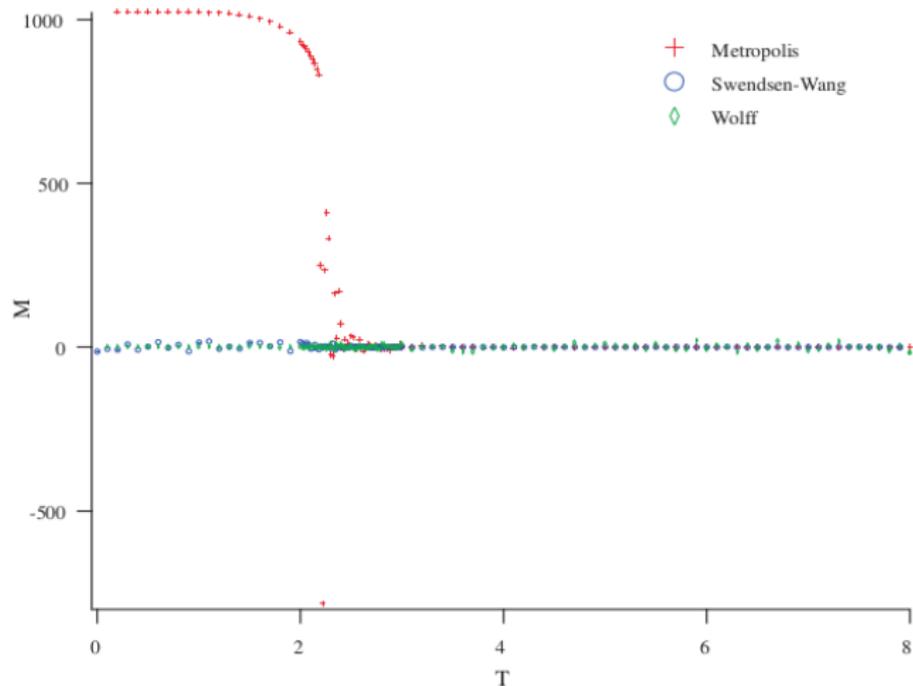

The new configuration  
The droplet contour is  
still shown, though the  
bonds are eliminated  
after flipping

- ▶ On the boundary:  $n_{\text{same}}$  spins parallel and  $n_{\text{diff}}$  antiparallel.

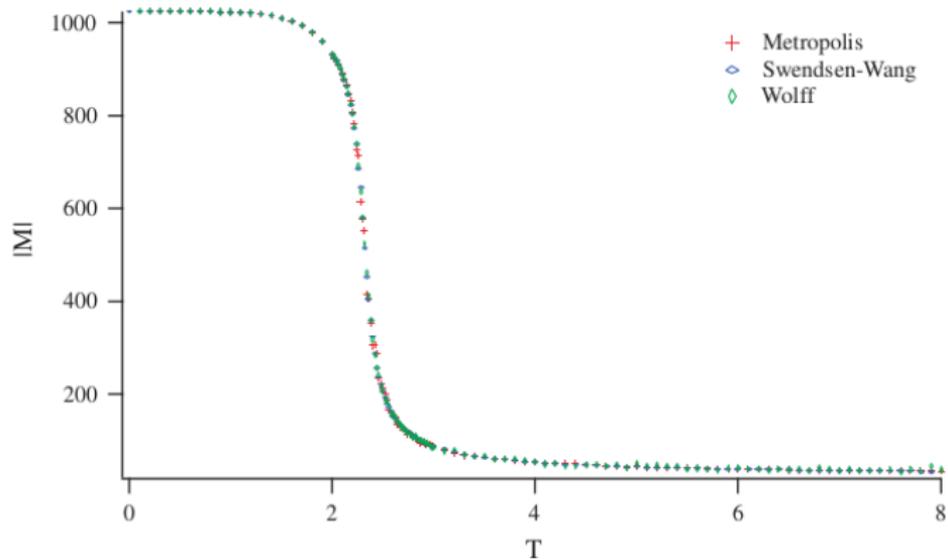

$$\begin{aligned} A(x \rightarrow x') &= \min \left\{ 1, \frac{e^{\beta J(n_{\text{diff}} - n_{\text{same}})} (1 - p_B)^{n_{\text{diff}}}}{e^{\beta J(n_{\text{same}} - n_{\text{diff}})} (1 - p_B)^{n_{\text{same}}}} \right\} \\ &= \min \left\{ 1, \frac{e^{-2\beta J n_{\text{same}}} (1 - p_B)^{n_{\text{diff}}}}{e^{-2\beta J n_{\text{diff}}} (1 - p_B)^{n_{\text{same}}}} \right\} \end{aligned}$$

- ▶ It gives:  $p_B = 1 - \exp(-2\beta J)$ .

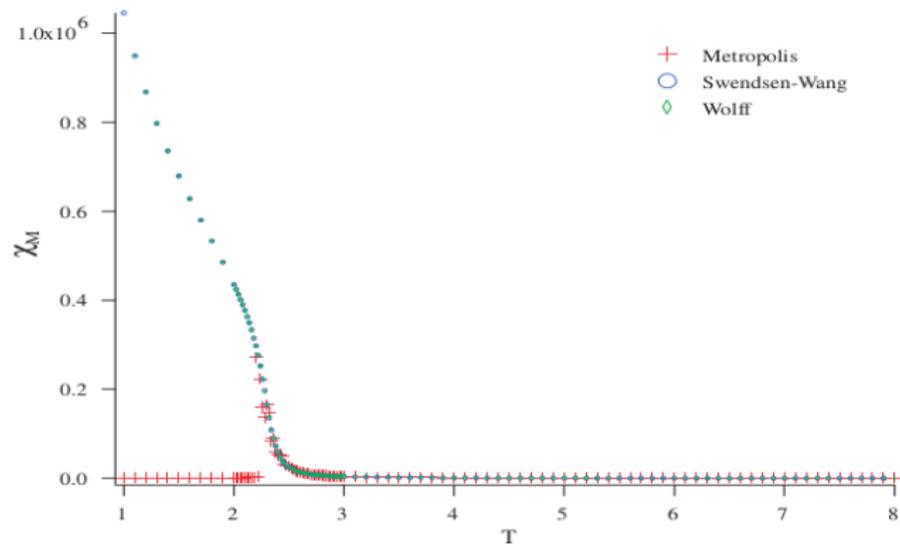

# Comparison magnetization

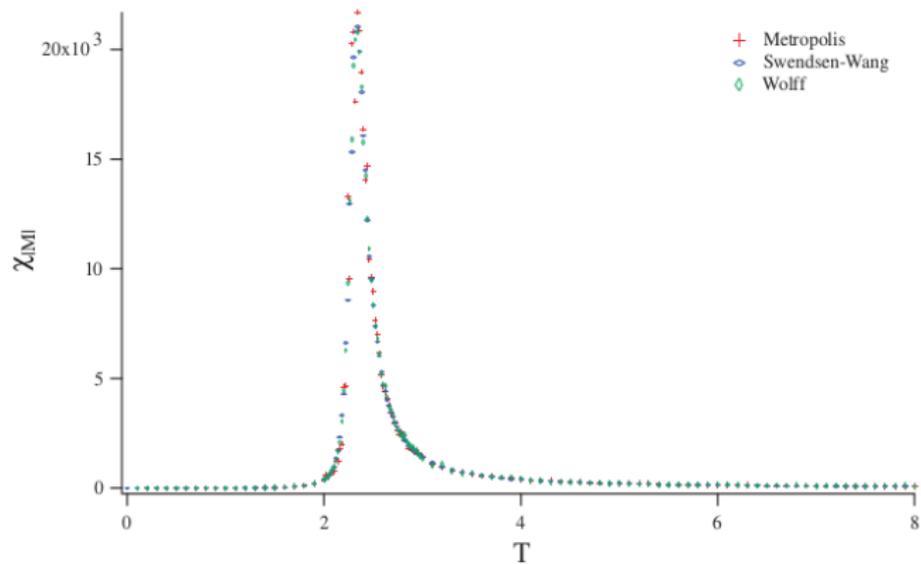

# Comparison magnetization

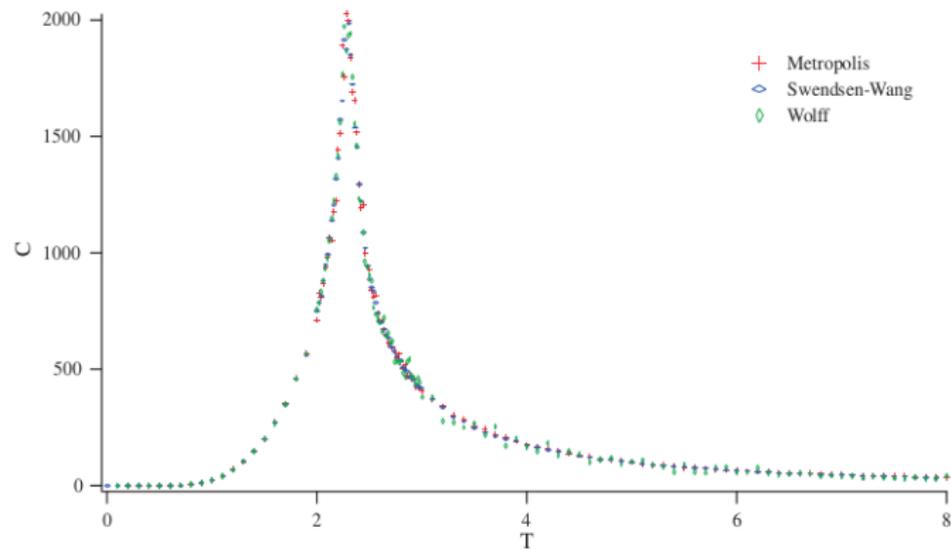

# Comparison magnetization

# Comparison magnetization

# Comparison magnetization

# Other ensembles

## Microcanonical ensemble

- ▶ Daemon with bag with tolerance (both directions)
  - ▶ Pick a move, and calculate energy change
  - ▶ If energy change does not fit into bag reject it
  - ▶ Otherwise add energy change to bag
- ▶ In case of conservation the dynamic exponent  $z$  is larger!

## Other ensembles

### Conserved order parameter: Kawasaki dynamics

- ▶ Elementary step:
  - ▶ Exchange up-down spin pairs (can be anywhere) simultaneously
  - ▶ Apply Metropolis to net energy change!
  - ▶ Diffusive dynamics is more physical: pick neighboring spins
- ▶ In case of conservation the dynamic exponent  $z$  is larger!

## Calculation of the entropy, free energy, etc.

- ▶ Equilibrium statistical physics: From  $F$  we can calculate everything
- ▶ In simulations  $F$  and  $S$  cannot be measured directly
- ▶  $F = E - TS$  so one of them is enough ( $E$  and  $T$  are known)
- ▶ Solution:  
Calculate the specific heat!

$$C = k_B T^2 \langle (\Delta E)^2 \rangle$$

- ▶ The energy fluctuations are measurable
- ▶ Since

$$C = T \frac{\partial S}{\partial T}$$

We have

$$S(T) = S(T_0) + \int_{T_0}^T \frac{C(T')}{T'} dT'$$

## Calculation of the entropy, free energy, etc.

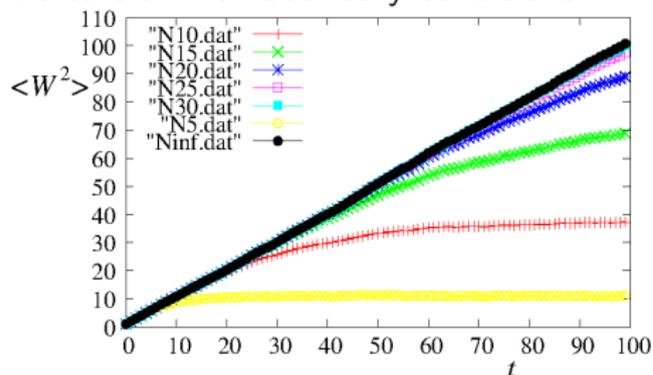

- ▶ In many cases derivative of the entropy is needed so  $S(T_0)$  is not important in

$$S(T) = S(T_0) + \int_{T_0}^T \frac{C(T')}{T'} dT'$$

- ▶ From third law of thermodynamics:  $S(T = 0) = 0$ .

# Diffusion

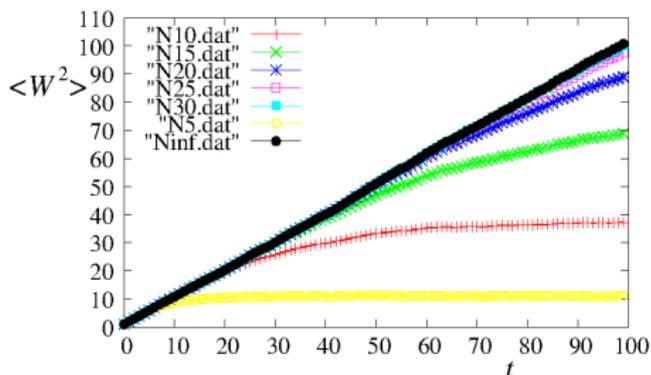

- ▶ On normal lattice exactly solvable
- ▶ Otherwise e.g. Monte Carlo kinetics. E.g. 1D
  - ▶ With probability  $1/2 \rightarrow$  go right
  - ▶ With probability  $1/2 \rightarrow$  go left
  - ▶ Be careful with boundary conditions

- ▶ Can easily be biased
- ▶ Can be simulated on spurious lattices, e.g. Percolation clusters

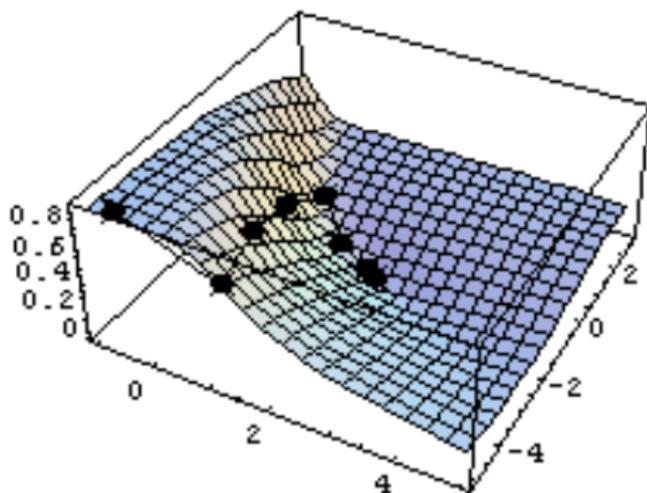

# Diffusion

- ▶ Solution for diffusion on finite lattice:
- ▶ Count steps in both directions
- ▶ The net move is  $W = n_+ - n_0$
- ▶ Use ensemble average
- ▶ Plot  $\langle W^2 \rangle$  vs.  $t$

# Optimization

- ▶ General problem of finding the ground state
- ▶ Phase-space:
- ▶ Arbitrary number of dimensions
- ▶ Methods:
  - ▶ Steepest Descent
  - ▶ Stimulated Annealing
  - ▶ Genetic algorithm

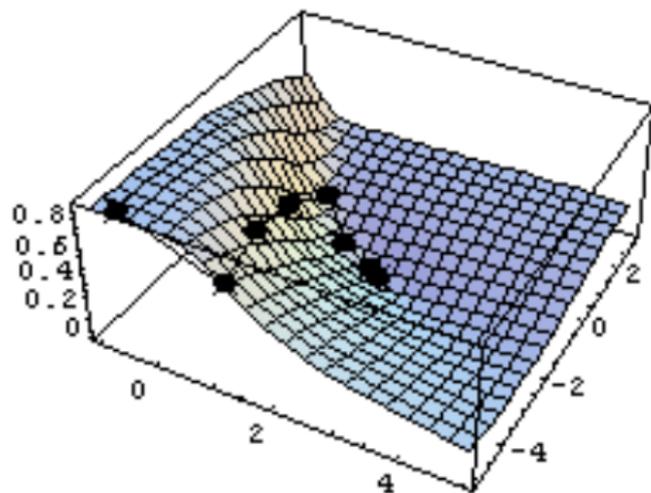

## Gradient based optimization

- ▶ Given  $f(\mathbf{x})$ , with  $\mathbf{x} = \{x_1, x_2, \dots, x_n\}$
- ▶ Gradient  $\nabla f(\mathbf{x}) \equiv \mathbf{g}(\mathbf{x}) = \{\partial_1 f, \partial_2 f, \dots, \partial_n f\}$
- ▶ Second order partial derivatives: square symmetric matrix called the *Hessian matrix*:

$$\nabla^2 f(\mathbf{x}) \equiv H(\mathbf{x}) \equiv \begin{pmatrix} \partial_1 \partial_1 f & \dots & \partial_1 \partial_n f \\ \vdots & \ddots & \vdots \\ \partial_1 \partial_n f & \dots & \partial_n \partial_n f \end{pmatrix}$$

# General Gradient Algorithm

1. Test for convergence
2. Compute a search direction
3. Compute a step length
4. Update  $x$

## Steepest descent algorithm

1. Start from  $\mathbf{x}_0$
2. Compute  $\mathbf{g}(\mathbf{x}_k) \equiv \nabla f(\mathbf{x}_k)$ . If  $\|\mathbf{g}(\mathbf{x}_k)\| \leq \varepsilon_g$  then stop, otherwise, compute normalized search direction  
$$\mathbf{p}_k = -\mathbf{g}(\mathbf{x}_k)/\|\mathbf{g}(\mathbf{x}_k)\|$$
3. Compute  $\alpha_k$  such that  $f(\mathbf{x}_k + \alpha\mathbf{p}_k)$  is minimized
4. New point:  $\mathbf{x}_{k+1} = \mathbf{x}_k + \alpha\mathbf{p}_k$
5. Test for  $|f(\mathbf{x}_{k+1}) - f(\mathbf{x}_k)| \leq \varepsilon_a + \varepsilon_r|f(\mathbf{x}_k)|$  and stop if fulfilled in two successive iterations, otherwise go to 2.

# Conjugate Gradient Method

1. Start from  $\mathbf{x}_0$
2. Compute  $\mathbf{g}(\mathbf{x}_k) \equiv \nabla f(\mathbf{x}_k)$ . If  $\|\mathbf{g}(\mathbf{x}_k)\| \leq \varepsilon_g$  then stop, otherwise Go to 5
3. Compute  $\mathbf{g}(\mathbf{x}_k) \equiv \nabla f(\mathbf{x}_k)$ . If  $\|\mathbf{g}(\mathbf{x}_k)\| \leq \varepsilon_g$  then stop, otherwise continue
4. Compute the new conjugate gradient direction  $\mathbf{p}_k = -\mathbf{g}_k + \beta_k \mathbf{p}_{k-1}$ , where

$$\beta = \left( \frac{\|\mathbf{g}_k\|}{\|\mathbf{g}_{k-1}\|} \right)^2$$

5. Compute  $\alpha_k$  such that  $f(\mathbf{x}_k + \alpha \mathbf{p}_k)$  is minimized
6. New point:  $\mathbf{x}_{k+1} = \mathbf{x}_k + \alpha \mathbf{p}_k$
7. Test for  $|f(\mathbf{x}_{k+1}) - f(\mathbf{x}_k)| \leq \varepsilon_a + \varepsilon_r |f(\mathbf{x}_k)|$  and stop if fulfilled in two successive iterations, otherwise go to 3.

# Modified Newton's method

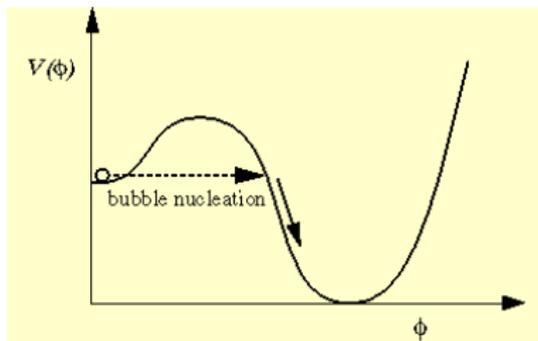

## Second order method

1. Start from  $\mathbf{x}_0$
2. Compute  $\mathbf{g}(\mathbf{x}_k) \equiv \nabla f(\mathbf{x}_k)$ . If  $\|\mathbf{g}(\mathbf{x}_k)\| \leq \varepsilon_g$  then stop, otherwise, continue
3. Compute  $H(\mathbf{x}_k) \equiv \nabla^2 f(\mathbf{x}_k)$  and the search direction  $\mathbf{p}_k = -H^{-1}\mathbf{g}_k$
4. Compute  $\alpha_k$  such that  $f(\mathbf{x}_k + \alpha\mathbf{p}_k)$  is minimized
5. New point:  $\mathbf{x}_{k+1} = \mathbf{x}_k + \alpha\mathbf{p}_k$
6. Go to 2.

# Nucleation

- ▶ There is a competition between the bulk free energy of the droplet and its surface energy
- ▶ There is a critical nucleus size above which the transition is very rapid.
- ▶ However, such a critical nucleus has to be created by spontaneous fluctuations – which takes (sometimes enormously long) time.

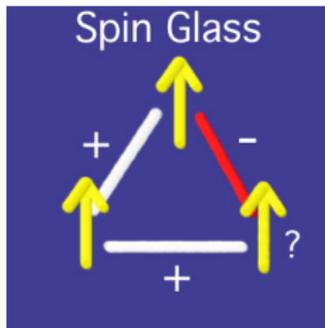

# Glassy behavior, frustration

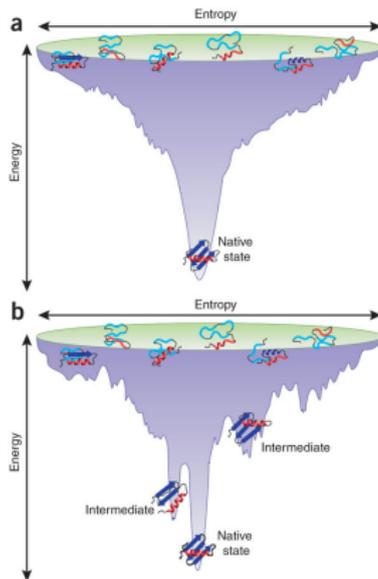

- ▶ Model glass: spin-glass:

$$H = -\frac{1}{2} \sum_{\langle i,j \rangle} J_{ij} S_i S_j$$

- ▶ where  $J_{ij}$  are random quenched variables with 0 mean (e.g.  $\pm J$  with probability half)

Rugged energy landscape.

# Rugged energy landscape

- ▶ Typical example NP-complete problems:
  - ▶ Traveling salesman
  - ▶ Graph partitioning
  - ▶ Spin-glass
- ▶ No full optimization is possible (do we need it?)
- ▶ Very good minimas can be obtained by optimization
  - ▶ Simulated annealing
  - ▶ Genetic algorithm

# Simulated annealing

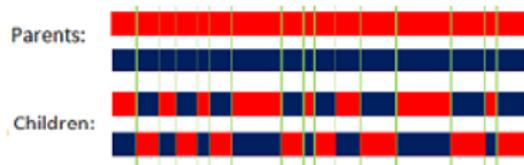

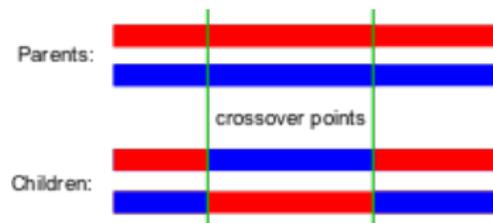

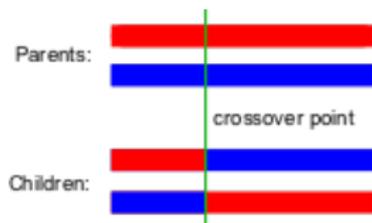

- ▶ Cool down the system slowly
- ▶ Warm up and down if needed, if the system quenched into a local minimum
- ▶ One needs a Hamiltonian and an elementary move
- ▶ Traveling salesman
  - ▶ Path length
  - ▶ Exchange two cities in the path
- ▶ Use Metropolis simulated annealing. ( $T \sim \text{alcohol}$ )

Demo movie

# Genetic algorithm: Reproduction

- ▶ Two parents and two children

With a probability of 0.5, children have 50% genes from first parent and 50% of genes from second parent even with randomly chosen crossover points.

## Genetic algorithm terminology

- ▶ Chromosome: Carrier of the genetic representation
- ▶ Gene: Smallest units in the chromosome with individual meaning
- ▶ Parents: Pair of chromosomes, which produce offsprings
- ▶ Population: Set of chromosomes from which the parents are selected. Its size should be larger than the length of the chromosome
- ▶ Selection principle: The way parents are selected (random, elitistic)
- ▶ Crossover: Recombination of the genes of the parents by mixing
- ▶ Crossover rate: The rate by which crossover takes place ( $\sim 90\%$ )
- ▶ Mutation: Random change of genes
- ▶ Mutation rate: The rate by which mutation takes place ( $\sim 1\%$ )
- ▶ Generation: The pool after one sweep.

# Genetic algorithm terminology
